Original Essay

There are two pie charts below, one shows how energy using in an average Australian household, and the other one shows the greenhouse gas emissions resulting from this energy use.

It is clear that the proportion of heating is the largest in Australian household energy use, and the water heating account for the most important part in Australian household greenhouse gas emissions. However cooling and lighting play a negligible role in both energy use and greenhouse gas emissions in Australian houses.

In Australian, 42% of household energy is produced by heating, which is only 15% in Australian household greenhouse gas emissions. While the water heating keeps a similar proportion in both Australian household energy use and Australian household greenhouse gas emissions at around 31%.

Other appliances, refrigeration, lighting and cooling account for 15%, 7%, 4% and 2% for household energy use individually, and nearly double the proportion of household greenhouse gas emissions in Australian, with the percentage of 28%, 14%, 8%, 3%.

Grammar & Spelling Check

Case 1

Original: how energy **using** in an average Australian household

Corrected: how energy **is used** in an average Australian household

Reason: Passive voice is required here. “Energy” cannot perform the action itself.

Case 2

Original: the water heating **account**

Corrected: water heating **accounts**

Reason: Subject-verb agreement error. “Water heating” is singular.

Case 3

Original: In **Australian**

Corrected: In **Australia**

Reason: “Australian” is an adjective, while “Australia” is the correct noun.

Case 4

Original: water heating **keeps** a similar proportion

Corrected: water heating **maintains** a similar proportion

Reason: “Maintains” is more natural and academic in Task 1 writing.

Case 5

Original: account for 15%, 7%, 4% and 2% for household energy use **individually**

Corrected: account for 15%, 7%, 4% and 2% of household energy use **respectively**

Reason: “Respectively” is the correct word when matching percentages to categories.

Case 6

Original: in Australian

Corrected: in Australia

Reason: Incorrect word form.

Case 7

Original: with the percentage of 28%, 14%, 8%, 3%

Corrected: with percentages of 28%, 14%, 8%, and 3%

Reason: More grammatically accurate and natural expression.

Score Improvement Suggestions

Case 1

Original: the most important part

Corrected: the largest proportion

Reason: “Largest proportion” is more suitable for describing chart data.

Case 2

Original: play a negligible role

Corrected: contribute only a small proportion

Reason: More precise and academic for IELTS Task 1.

Case 3

Original: keeps a similar proportion

Corrected: remains at a similar level

Reason: More formal and natural collocation.

Case 4

Original: nearly double the proportion

Corrected: represent significantly higher proportions

Reason: Avoids vague comparison and sounds more objective.

Vocabulary Enhancement

Case 1

Original: shows

Corrected: illustrates, presents, compares

Case 2

Original: the largest

Corrected: the highest proportion, the dominant category

Case 3

Original: play a negligible role

Corrected: make up a minimal share, contribute marginally

Case 4

Original: produced by heating

Corrected: consumed for heating, used for heating purposes

Corrected Essay

The two pie charts compare how energy is used in an average Australian household and the greenhouse gas emissions produced by this energy use.

It is clear that heating accounts for the largest proportion of household energy use in Australia, while water heating produces the highest percentage of greenhouse gas emissions. In contrast, cooling and lighting contribute only a small proportion in both categories.

In Australia, 42% of household energy is used for heating, whereas this activity is responsible for only 15% of greenhouse gas emissions. Meanwhile, water heating represents a similar proportion in both household energy use and greenhouse gas emissions, at around 30% and 32% respectively.

Other appliances, refrigeration, lighting, and cooling account for 15%, 7%, 4%, and 2% of household energy use respectively. However, these categories produce higher proportions of greenhouse gas emissions in Australia, at 28%, 14%, 8%, and 3% respectively.
